Prediction Model in Medical Science and Health Care

Jan Horas Veryady Purba, Muhamad Ratodi, Mumuh Mulyana, Soegeng Wahyoedi, Ririn Andriana, K. Shankar, Phong Thanh Nguyen

*Abstract***:** *The healthcare part has seen an incredible advancement following the improvement of new computer innovations, and that pushed this region to deliver increasingly restorative information, that which brought forth different fields of research. Numerous endeavors are done to adapt to the blast of therapeutic information on one hand, and to acquire valuable learning from it then again. To help in making decisions and to extract useful knowledge this incited specialists to apply all the specialized developments like predictive analytics, learning algorithms, machine learning and predictive analytics. In medical science to determine the risk of building up a disease the prediction models are used so that it can enable early treatment or prevention of that disease. To markers of future disposition to a disease multiple or single analyses are used.*

Keywords **:** *healthcare, computer innovations, predictive analytics, prediction models.*

I. INTRODUCTION

Due to few technological innovations in the area like cloud computing that moved the trial of consideration past the four dividers of the emergency clinic, and has made them accessible anyplace and whenever [1]. The classical surgery replaced by robotic surgery and laparoscopic surgery, on specific physiological conditions using simple devices that deliver results the smart home allow monitoring and patients self-care [2],   the field of medical has its incredible commitment in this storm of information. With the goal of monitoring using integrated sensors by using software or smart applications the body signals can analyze, it is like mHealth technologies that help new strategies for environmental, biological and behavioral data collection. To monitor the phenomena with a higher accuracy these include sensors. By multiplying electronic medical records and data sources every one of these developments took an interest to medical data explosion it contain biometric information, diagnostic Images and lab results that are stored and generated. To predict the most dangerous diseases such as heart disease, diabetes, breast cancer and motor neuron for prediction and classification there are using many algorithms.

Over time new treatment options, patient populations and healthcare outcomes are constantly changing [3].

Figure 1: Prediction methods for healthcare industry

II. HEALTHCARE PREDICTIVE MODELING

It can consider that the predictive modeling is a subset of concurrent analytics simultaneously that uses two or more kind of statistical analysis. By using a multivariate set of predictors to anticipate an outcome, event or behavior is the main objective of predictive modeling [4].

Figure 2: Healthcare Analytics

By analyzing patient and consumer preferences, demographics, lifestyles and psychographics the predictive models take these anticipations in the industry of healthcare. At particular audiences then the marketers of healthcare make target of outreach messaging and through specific channels it deliver [5].

III. PREDICTIVE MODELS BENEFITS IN HEALTHCARE

From patterns and correlations that found in large amount of patient and consumer the predictive models derive insights.
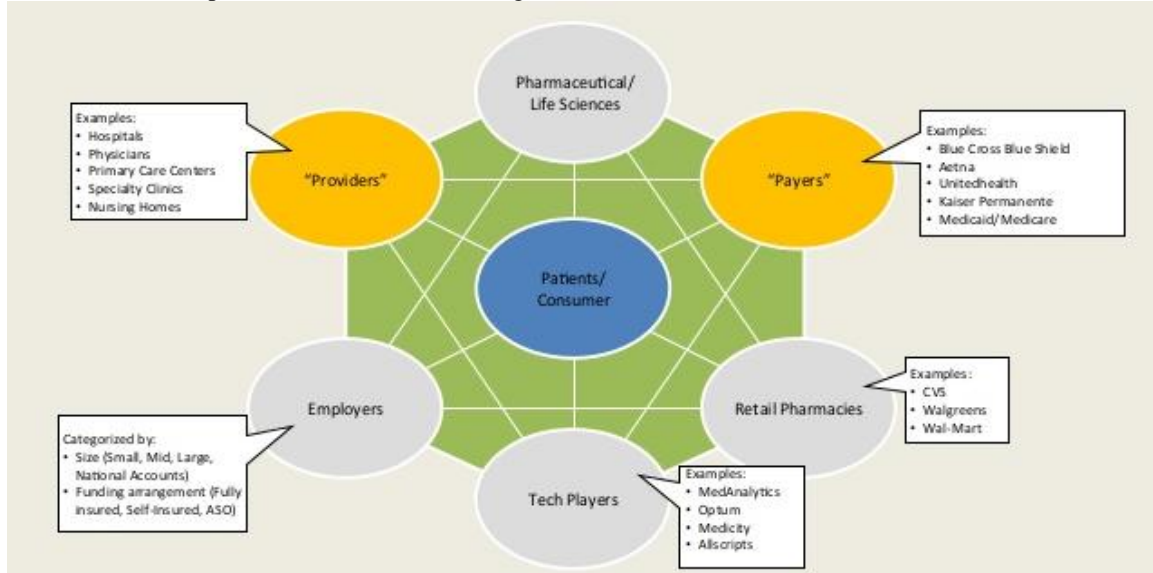

To optimization and inform campaign creation these insights used by healthcare marketers [6].

By focusing resources and spend with the organization on individuals most likely to incorporate the ROI improve the healthcare marketers by Predictive modeling. Because the general outreach campaigns use hyper-personalized elements like location-specific services this is more effective retention and acquisition strategy.

IV. PREDICTIVE ANALYTICS IN HEALTHCARE

In healthcare analytics the machine learning and Predictive analytics are growing rapidly in current days and perhaps it is most-hyped and most-discussed topic in healthcare. In many industries with a long history of success machine learning is a well-studied discipline [8]. For improving supply chain efficiencies, patient care hospital administration and chronic disease management from this previous success to jumpstart the utility of predictive analytics the healthcare can learn useful subjects. For healthcare systems the opportunity that recently exists is to define the meaning of predictive analytics to them and to build the improvements how can use it most effectively.

For the sake of making a prediction are a waste of money and time however, predictions made solely. When the knowledge can be transferred into action prediction is most useful in healthcare and other industries. The readiness to intercede is the way to outfitting the intensity of real-time data and historical data. Within the workflow and the same system where the pattern happens both the intervention and predictor must be integrated to best value and gauge efficacy.

Figure 4: Tools of healthcare predictive analytics [9]

V. MACHINE LEARNING AND PREDICTIVE ANALYTICS

To establish a fundamental analytic and data infrastructure upon which it creates is the most significant beginning point. Purposely however rapidly move association up the degrees of the Healthcare Analytics Adoption Model. In healthcare this model for assessing the adoption of analytics a similar approach describes and from the HIMSS EHR Adoption Model this model draws upon lessons. This model beginning a level 1 [10] establishment of an enterprise data warehouse combined an integrated with a basic arrangement of discovery and foundational analytic applications.

Figure 6: use of data in predictive analytics

1. Begin with Analytics Platform and an Integrated Data Warehouse

To manage patients across the whole continuum it needs data. An EDW (enterprise data warehouse) platform is needed for this. To make sense of the data and systematically integrate an EDW is consider as central platform on which it can develop an approach of scalable analytics.

2. Predictive Modeling three Basic Steps use

The predictive modeling process steps are given below:

   a. In first phase the problem that wants to address is clearly defined, then necessary initial data collected and various different algorithm methods evaluate.
   b. By selecting the best performing models and to validate the approach with a separate data set testing is done in second stage.
   c. In a real world setting at the last step it run the model

Figure 7: three steps of predictive modeling [11]

It is necessary for the healthcare providers to join with other groups that have knowledge of commercial and leading academic and to develop appropriate prediction models have the experience.

VI. CAN IMPROVE HEALTHCARE BY PREDICTION MODEL

1. To implement the prediction models the predictive analytics permit researchers that can be more efficient and accurate over the time and do not require thousands of cases.

In the studies of huge population, even little contrasts can be "statistically significant." Researchers comprehend that arbitrarily relegated case control studies are better than observational examinations, however regularly it is essentially not attainable to do such a plan. From enormous observational examinations, the little yet measurably noteworthy contrasts are regularly not clinically huge. The media, uninformed of research subtleties, may then concentrate on those little yet measurably noteworthy discoveries, persuading and some of the time startling people in general. Specialists likewise are to be faulted as in some cases they themselves don't comprehend the contrast between clinical significance and statistical significance [12].

2. The Accuracy of diagnoses increase by prediction models

Doctors can utilize prediction model to enable them to make increasingly precise diagnoses. For instance, when patients go to the ER with chest torment, it is frequently hard to tell whether the patient ought to be hospitalized. On the off chance that the specialists had the option to answers inquiries regarding the patient and his condition into a framework with a tried and exact prescient calculation that would survey the probability that the patient could be sent home securely, at that point their own clinical decisions would be supported. The forecast would not supplant their decisions but instead would help [13].

3. For medications to best meet the needs of the public predictive analytics model used by Pharmaceutical companies.

There will be motivations for the pharmaceutical business to create drugs for ever littler gatherings. Old prescriptions, dropped in light of the fact that they were not utilized by the majority, might be brought back in light of the fact that medication organizations will discover it monetarily practical to do as such. As it were, past enormous mass drugs are sure to be utilized less in the event that they are found not to help a considerable lot of the individuals who were endorsed them. Less utilized drugs will be financially rewarding to resuscitate and create as research can foresee the individuals who may profit by them. For instance, if 25,000 individuals should be treated with a drug "shotgun-style" so as to spare 10 individuals, at that point much waste has happened. All drugs have undesirable symptoms [14].

4. With predictions concerning insurance product costs the predictive analytics can provide employers and hospitals.

There will be numerous advantages in personal satisfaction to patients as the utilization of prescient examination increment. Possibly people will get medicines that will work for them, be recommended meds that work for them and not be given pointless drugs since that prescription works for most of individuals. The patient job will change as patients become progressively educated customers who work with their doctors cooperatively to accomplish better results. Patients will wind up mindful of conceivable individual wellbeing dangers sooner because of cautions from their genome investigation, from prescient models transferred by their doctors, from the expanding utilization of applications and therapeutic gadgets (i.e., wearable gadgets and checking frameworks), and because of better precision of what data is required for exact forecasts. They at that point will have choices to make about ways of life and their future prosperity. [15]

5. For the individual patients according to the condition the Predictive analytics model provides physicians.

Evidence-based medicine (EBM) is a positive development and gives more help than basic hunches for doctors. In any case, what works best for the center of a typical dispersion of individuals may not work best for an individual patient looking for treatment. Dad can help specialists choose the precise medications for those people. It is inefficient and possibly hazardous to give medicines that are not required or that won't work explicitly for a person. Better findings and more focused on medications will normally prompt increments in great results and fewer assets utilized, including the specialist's time.

6. To public health and medicine prevention the Predictive analytics model helps

With early intercession, numerous infections can be avoided or improved. prediction model, especially inside the domain of genomics, will enable essential consideration doctors to distinguish in danger patients inside their training. With that learning, patients can make way of life changes to keep away from dangers.

VII. CONCLUSION

The healthcare part has seen an incredible advancement following the improvement of new computer innovations, and that pushed this region to deliver increasingly restorative information, that which brought forth different fields of research. By using a multivariate set of predictors to anticipate an outcome, event or behavior is the main objective of predictive modeling. By analyzing patient and consumer preferences, demographics, lifestyles and psychographics the predictive models take these anticipations in the industry of healthcare. In healthcare analytics the machine learning and Predictive analytics are growing rapidly in current days and perhaps it is most-hyped and most-discussed topic in healthcare. In many industries with a long history of success machine learning is a well-studied discipline.
